Basics of Design Pattern I

30 years ago

- A **design pattern** is a practical proven solution to a recurring design problem in software engineering.
- A **design pattern** is not a finished design, just flexible or reusable parts of a complete solution.
- Created (or discovered) for expert developers, and had been matured by non-expert developers, they are like food recipes, or play tik-tik-toe.
- There are 23 design patterns, classified in three categories: creational, structural, & behavioral patterns.
- Reported by the Gang of Four (GoF) in 1994, in the book Design Patterns: Elements of Reusable Object-Oriented Software.

customize

Basics of Design Pattern I

- A **design pattern** is a **practical proven solution** to a **recurring design problem** in software engineering.
- A **design pattern** is not a finished design, just **flexible** or **reusable parts** of a **complete solution**.
- Created (or discovered) for **expert developers**, and had been matured by **non-expert developers**, they are like **food recipes**, or **play tik-tik-toe**.
- There are **23 design patterns**, classified in *three categories*: **creational**, **structural**, & **behavioral** patterns.
- Referred by the **Gang of Four (GoF)** in 1994, in the book **Design Patterns: Elements of Reusable Object-Oriented Software**.

Basics of Design Pattern I

- A **design pattern** is a **practical proven solution** to a **recurring design problem** in software engineering.
- A **design pattern** is not a finished design, just **flexible** or **reusable parts** of a **complete solution**.
- Created (or discovered) for **expert developers**, and had been matured by **non-expert developers**, they are like *food recipes*, or *play tik-tik-toe*.
- There are 23 design patterns, classified in *three categories*:
→ **creational**, **structural**, & **behavioral** patterns.
- Reported by the Gang of Four (GoF) in 1994, in the book **Design Patterns: Elements of Reusable Object-Oriented Software**.

Outline

- 1 Design Patterns
- 2 **Creational Patterns**
- 3 Structural Patterns
- 4 Behavioral Patterns
- 5 Anti-Patterns & Code Smells

Basic Concepts

- **Intent:** Separate the construction of a complex object from its representation so that the **same construction process** can create different representations.

- **Motivation:**

- **Problem:** An application needs to create instances of a class, but the class is abstract and has many possible implementations.
- **Solution:** Provide different object creation mechanisms, which **allow** the client to create the object without knowing the actual implementation. This increase flexibility and reuse of code.

The Rule of Least Knowledge

Builder Pattern — Concepts

SOLID

- It is a **pattern** that lets **construct** **complex object step by step**. The idea is to **create different representations** of an object using the **same construction code**.
- A **problem** is work with a **class** that has **many attributes** and it is **difficult** to **create an instance** of it. It gets **worse** when there are **many possible representations** of the object because some are **optional**.
- The **solution** is to **encapsulate** the object **construction** and **use separate methods** to **add** or **build** the object **attributes**.

Prototype Pattern — Concepts

- It is based on **copy** of an **existing object**. It is used when the **type of objects** to create is determined by a **prototypical instance**, which is **cloned** to produce new objects.
- Remember, **clone** is **not just copy** an object, it is **create** a new **object** with the **same attributes** and **values** of the original object.
- It solves the **problem** of **copy the private attributes** of an object. So, you could create a **copy including the hidden logic**.

.clone()

Singleton Pattern — Concepts

db connector
- framework

- In an attempt to **reduce memory consumption**, this pattern ensure that a **class** has only **one instance** and provide a **global point of access** to it.
- It is used when you need to **control** the **number of instances** of a class, so **just one** class instance is allowed **across all** the application. Also it allows to **apply** the concept of **lazy creation**.
- It is **pretty simple**: just create a class with a method that **creates** a new **instance** of the class if one does not exist. If an instance **already exists**, it returns a **reference** to that object.
- It **violates** the **Single Responsibility Principle** and the **Open/Closed Principle**. Also, **internal instance** and **get method** are **static**.
- **Not** a very **good idea** if you are using a **multi-threading** application, could be issues trying to **access a shared** single object.

Singleton Pattern — Classes Structure

Think in a circle room with several doors but just one doorman.

Figure: Singleton Pattern Class Diagram

Factory Pattern — Concepts

- It is **pattern** based on a **superclass** and the **subclasses** could alter the **type of objects** to be created.
- One of the **most common** design pattern used, is **simple**, **powerful** and **flexible**. It is **used** with **many other design patterns**.
- It lets make **simple** a **complex code**. If you have **groups of objects** that are **created in a similar way**, the **factory method** is the **best choice**.
- The **client** just needs to **interact** with the **factory**, and the **factory** will **create the object**. The **client** does **not need to know** the actual **implementation of the object** (or the **subclasses**).

Factory Pattern — Classes Structure

It is like to watch **Charlie and the Chocolate Factory**.

Figure: Factory Pattern Class Diagram

Create Product(type):
 if (type == "A")
 return Prod A;
 else if (type == "B")
 return Prod B;
 }
 Demo time!
 else if (type == "Car")
 return Car();

Abstract Factory Pattern — Concepts

- This is a pattern that lets you produce families of related objects without specifying their concrete classes.
- It is a super factory that creates other factories. It is used when you have a super class that can create subclasses and the subclasses can create objects.
- Also this pattern allows to keep the client code decoupled from the actual objects in the system. Keep old code when you need to add new representations.
- It is used when you have many objects that can be grouped in families.

Conclusions

- There are a few ways to **create objects** inside an application in a **pretty efficient way**. You just need to think about it and **choose the best one** for your application.
- You **could combine** these **patterns** to create a **more complex** and **flexible application**. However, you need to be **careful** with the **complexity** of the application.
- The **Builder pattern** is used to create a **complex object step by step**.
The **Prototype pattern** is used to create **a new object by copying an existing object**.
- ✓ The **Singleton pattern** is used to create **just one instance** of a class.
- ✓ The **Factory pattern** is used to create objects in a simple way.
- The **Abstract Factory pattern** is used to create **families of objects**.

Outline

- 1 Design Patterns
- 2 Creational Patterns
- 3 Structural Patterns**
- 4 Behavioral Patterns
- 5 Anti-Patterns & Code Smells

Basic Concepts

- **Intent:** Describe how objects are connected to each other. These patterns are related to the design principles of decomposition and generalization.
- **Motivation:**
 - **Problem:** A system is composed of multiple classes that interact with each other. The system becomes complex due to the relationships between these classes.
 - **Solution:** Structural class patterns use inheritance to compose interfaces or implementations.

inheritance

decrease complexity

Bridge Pattern — Concepts

- When there is a **very large class**, this **pattern** lets **split** it into **two separate hierarchies** based on **abstraction** and **implementation**.
- Also, it helps when you want to **combine** two different but **related classes**, and you want to keep them **independent**.
- This **pattern** **solves** this problem **avoiding inheritance** and trying to **switch** to **object composition**.

ML. method()

ML bridge.method 2();

Composite Pattern — Concepts

- Compose objects into **tree structures** to represent **part-whole hierarchies**.
- **Composite** lets clients **treat individual objects and compositions of objects uniformly**, based on **tree nodes** concepts.
- It **makes sense** to use this **pattern** if the **problem** could be **represented as a tree**.
- In this case, it means to think in **polymorphism**.

Proxy Pattern — Concepts

- This **pattern** lets to provide a **substitute** for an **object**. In this way, **access** could be controlled.
- It is **useful** when you want to **add a level of indirection** to **control access** to an object. It is like a **middle layer** without **affecting** previous logic.
- It is **useful** when you want to **reduce memory** used in a service, similar to think in **cache memory**. Also, it lets **add additional logic** (like **logging** or **security**) to an existing logic **without** change original class.

Flyweight Pattern — Concepts

- This **pattern** lets you use **sharing** to support large numbers of fine-grained objects efficiently.
- The idea to **reuse objects** parts with **immutable** state. This lets share common parts and reduce memory usage.
- It **makes sense** to use it in **problems** with **high memory** consumption, but with **repeated objects**, i.e. some *simulations*.

Adapter Pattern — Concepts

- This **pattern** is pretty simple, it just attempts to **convert** the **interface** of a class into **another interface** clients expects.
- It is useful when you want to **reuse** an existing **class**, but its **not compatible** with the **rest of your code**, or at least where you need it.
- It increases **compatibility**, and lets define an architecture based on **interfaces** and **not** on **concrete classes**.

Decorator Pattern — Concepts

- This **pattern** lets you **attach** additional **functionalities** to an object dynamically.
- It is useful when you want to **add** new **functionalities** to an object **without affecting** its **original logic**. Indeed, you could add same additional functionalities to different objects.
- Here the concept of **wrap** an **object** with **another object** is important. One **object** could have some **behaviors** from another object **without inheritance**. It is because in this case the **relation** is based on **object-oriented aggregation**.

Decorator Pattern — Classes Structure

It is like (Dr. Strange) and his Cloak of Levitation.

Figure: Decorator Pattern Class Diagram

Demo time!

Facade Pattern — Concepts

- This **pattern** provides a **unified interface** to a set of classes that could be **group** into a **subsystem**. *→ API Gateway*
- It is useful when you want to **define a high-level interface** that makes the **subsystem** **easier to use**. It means, **hide** any **complex logic** and let the client use a **simple interface**. *→ Frameworks*
- It is normal when you want to **reduce the dependencies**. The **client** just **interacts** with the **facade**, and the **facade** interacts with the **subsystem**.
- You could **add complexity** at the subsystem and **client will not be affected**, it **increases flexibility**. At most, there will be **more new functionalities** to be exposed to the client.

Facade Pattern — Classes Structure

You are the only one who knows how to **find something** in your bedroom.

Figure: Facade Pattern Class Diagram

Demo time!

Conclusions

- **Structural patterns** are useful to describe how objects are connected to each other.
- They are related to the **design principles** of **decomposition** and **generalization**.
- You could **fix a lot of problems** with these **patterns** as a nice solution. However, be **careful** with the **complexity** of the solution.
- The idea is to make the **system** **flexible**, **reusable**, and **easy to maintain**.

Outline

- 1 Design Patterns
- 2 Creational Patterns
- 3 Structural Patterns
- 4 Behavioral Patterns**
- 5 Anti-Patterns & Code Smells

Basic Concepts

- **Intent:** Focus on how classes distribute responsibilities among them, and at the same time each class just does a single cohesive function. It is like a F1 Pits Team, each one has a **single responsibility**, but all together creates a complete team workflow. → 2-3 seg.
- **Motivation:**
 - **Problem:** A system should be configured with multiple algorithms and a system should be independent of how its operations are performed.
 - **Solution:** Define each algorithm, encapsulate each one, and make them work together.

high cohesion
low coupling

Iterator Pattern — Concepts

- The **Iterator pattern** is a **behavioral** pattern that **allows sequential access** to the elements of an **aggregate** object without exposing its underlying representation.
- The **Iterator pattern** is used when you want to **provide a standard** way to **iterate over a collection** and **hide** the implementation details of *how* the collection is traversed.

Memento Pattern — Concepts

- The **Memento** pattern is a behavioral pattern that lets you save and restore the previous state of an object without revealing the details of its implementation. / checkpoints *minimax*
- The **Memento** pattern is used when you want to provide the ability to restore an object to its previous state (undo). *Ctrl + Z*
- The **Memento** pattern is used when you want to provide a rollback mechanism in case of errors or exceptions. → *git / change history*

Strategy Pattern — Concepts

- The **Strategy pattern** is a **behavioral** pattern that lets you define a **family of algorithms**, put each of them into a **separate class**, and make their **objects interchangeable**. *sort*
- The **Strategy pattern** is used when you want to define a **class** that will have one **behavior** that is **similar to other behaviors** in a list.
- The **Strategy pattern** is used when you **need** to use **one** of **several** behaviors dynamically.

Template Pattern — Concepts

- The **Template pattern** is a **behavioral** pattern that defines the program **skeleton** of an **algorithm** in the superclass but lets **subclasses** **override** specific steps of the **algorithm** without changing its structure.
- The **Template pattern** is used when you want to let **clients** **extend** only **specific steps of an algorithm**, but **not the whole algorithm** or its structure.

Recipes

Rice drinks

Interface + mother class

State Pattern — Concepts

- The **State** pattern is a behavioral pattern that lets an object alter its behavior when its internal state changes. It appears as if the object changed its class. *attributes*
- The **State** pattern is used when you want to have an object that behaves as if it were an instance of a different class when its internal state changes.
- The **State** pattern is used when you want to avoid a large number of conditional statements in your code.

Mediator Pattern — Concepts

- The **Mediator** pattern is a **behavioral** pattern that lets you reduce chaotic dependencies between objects. The pattern restricts direct communications between the objects and forces them to collaborate only via a mediator object.
- The **Mediator** pattern is used when you want to **reduce the number of dependencies** between your classes.
- The **Mediator** pattern is used when you want to **simplify the communication** between objects in a **system**.

Command Pattern — Concepts

- This **pattern** is pretty simple, it just attempts to **convert** the **interface** of a class into **another interface** **clients** **expects**.
- It is useful when you want to **reuse** an existing **class**, but its **not compatible** with the **rest of your code**, or at least where you need it.
- It increases **compatibility**, and lets define an **architecture** based on **interfaces** and **not** on **concrete classes**.

Chain of Responsibility Pattern — Concepts

- The **Chain of Responsibility pattern** is a **behavioral** pattern that lets you pass **requests** along a **chain of handlers**. Upon receiving a **request**, each **handler** decides **either** to **process the request** or to **pass it along the chain**.
- The **Chain of Responsibility pattern** is used when you **want** to give **more** than one object a **chance** to **handle** a **request**.
- The **Chain of Responsibility pattern** is used when you want to pass a request to one of **several objects** **without** **specifying** the receiver explicitly.

Chain of Responsibility Pattern — Classes Structure

A lot of **quality reviewers** are needed to **approve** a **high quality product**.

Figure: Chain of Responsibility Pattern Class Diagram

Demo time!

Observer Pattern — Concepts

- The **Observer** pattern is a **behavioral** pattern that lets you define a **subscription mechanism** to **notify** multiple objects about any **events that happen** to the object they're observing.
- The **Observer pattern** is used when you **need** many **other objects** to receive an **update** when **another object changes**.
- The **Observer pattern** is used when an object **should be able to notify** other objects **without making assumptions** about who these objects are.

Observer Pattern — Classes Structure

When you have a lot of **eyes looking** at you, you are an **observer**.

Figure: Observer Pattern Class Diagram

Demo time!

Conclusions

- **Behavioral Patterns** are a set of *patterns* that focus on **how** objects **distribute responsibilities** among them.
- **Behavioral Patterns** are *used* when you want to provide a standard way to **iterate** over a **collection**, save and **restore the previous state** of an object, define a **family of algorithms**, *alter an object's behavior* when its **internal state changes**, **reduce chaotic dependencies** between objects, turn a **request into a stand-alone object**, define a **subscription mechanism** to notify multiple objects about any events that happen to the object they're observing.
- **Behavioral Patterns** are **not recommended** when you have a **system** that **doesn't change**, or you have a **system** that **doesn't have a lot of** objects.

Outline

- 1 Design Patterns
- 2 Creational Patterns
- 3 Structural Patterns
- 4 Behavioral Patterns
- 5 Anti-Patterns & Code Smells

Bad Coding

- **Bad Coding** is a **software design problem** that states that the code is not well written.
- If the *software* has **bad coding**, it is not **maintainable** and **extensible**.
- **Spaghetti Code** is a bad coding that is **difficult to understand** and **maintain**.
- **Bad practices** as **copy-paste code**, **hardcoded values**, and **magic numbers** are *bad coding*.

Code Quality

- **Code Quality** is a process to validate that the **code is well written**.
- **Metrics** as **code coverage**, **cyclomatic complexity**, and **code smells** are used to measure the **code quality**.
- **Code Review** is a process to validate that the code is well written by another developer.
- **Unit Testing** is a process to validate that a small fragment of code is working as expected

Stupid Deployments!

**“No pasa
nada, así
mándalo a
producción”
by
Crowdstrike**

Anti—Patterns

- **AntiPatterns** are **bad practices** in **software design**.
- An **AntiPattern** is a **pattern** that is *commonly used* but is **ineffective** and **counterproductive**.
- **AntiPatterns** are used to *identify* and **fix bad practices** in **software design**.
- **Techniques** to avoid AntiPatterns are **refactoring**, **code review**, and **unit testing**.

Identify and Fix Code Smells

- **Identify Code Smells** is a process to find the **bad coding** in the **software**.
- **Fix Code Smells** is a process to correct the **bad coding** in the **software**.
- To *identify* and *fix* **code smells**, the **software** should be **refactored**.
- **Refactoring** is a process to **improve** the **software** without changing the **behavior**. A good book is *Refactoring: Improving the Design of Existing Code*, by **Martin Flower**.
- Techniques like **code review** and **unit testing** are used to *identify* and *fix* **code smells**.
- **Linters** and **static analysis tools** are used to **identify** and **fix code smells**.

Examples of Code Smells I

- **Comments** are used to explain the code. It could be a **code smell** because the code maybe is not **self-explanatory**. Should have a equilibrium of comments.
- **Long Methods** and **Long Classes** (Good Classes or Black-Hole Classes) are used to group the code. It could be a **code smell** because the method or the class maybe is doing too much. Remember: **Single Responsability** and **Separation of Concerns**.
- **Magic Numbers** are used to hardcode values. It could be a **code smell** because the value maybe is not **modularized**. Use **constants** instead.
- **Duplicated Code** is used to reuse the code, maybe in blocks of code that are similar. It could be a **code smell** because the code maybe is not **modularized**. DRY (*don't repeat yourself*) principle.

Examples of Code Smells II

- **Dead Code** is used to keep the code that is not used. It could be a **code smell** because the code maybe is not **maintainable**. Remove the code that is not used.
- **Data Classes** are used to group the data. It could be a **code smell** because the class contains only data and not real functionality. Use **encapsulation** instead, and not just **getters & setters**.
- **Feature Envy** consist in a method that uses more the data of another class than its own data. It could be a **code smell** because it increases the **coupling** between the classes. Use **encapsulation** instead, or a **design pattern** like **Observer**.
- **Data Clumps** consist in a group of data that is used together. It could be a **code smell** because the data maybe is not **modularized**. Use **encapsulation** instead, or a **design pattern** like **Composite**.

Examples of Code Smells III

- **Refused Bequest** occurs when a class inherits from another class but does not use the inherited methods. It could be a **code smell** because the class maybe is not **modularized**. Use **composition** instead, or a **design pattern** like **Template**.
- **Switch Statements** occurs when a class has a lot of switch statements. It could be a **code smell** because the class maybe is not **modularized**. Use **polymorphism** instead, or a **design pattern** like **Strategy**.
- **Long Parameter List** consists in a **method** that has a **lot of parameters**. It could be a **code smell** because the method maybe is doing too much or is hard to call. Use **parameter objects** instead.
- **Divergent Change** occurs when a class is changed for different reasons. It could be a **code smell** because the class maybe is not **modularized**. Use **composition** instead, or a **design pattern** like **Strategy**.

Examples of Code Smells IV

- **Shotgun Surgery** is a common problem in **software design**. It occurs when a change in a class requires changes in many other classes. It could be a **code smell** because the class maybe is not **modularized**. Use **composition** instead, or a **structural design pattern**.
- **Innapropriate Intimacy** occurs when a class has a lot of dependencies with other classes. It could be a **code smell** because the class maybe is not **modularized**. Use **composition** instead, or a **design pattern** as proxy. Remember the **Principle of Least Knowledge**.
- **Message Chains** violates the **Law of Demeter**. It occurs when a class calls a method of another class that calls a method of another class, and so on. It could be a **code smell** because the class maybe is not **modularized**. Use **encapsulation** instead, or a **design pattern** like **Observer**.

Examples of Code Smells V

- **Primitive Obsession** consists in the use of **primitive types** instead of **objects**. It could be a **code smell** because the code maybe is not using right **abstractions**. Use **abstract types** instead.
- **Speculative Generality** consists in the use of **design patterns** that are not needed, or to create **interfaces** thinking maybe those could be useful in the future. It could be a **code smell** because the code maybe is not **modularized**. Use **design patterns** only when needed.

Outline

- 1 Design Patterns
- 2 Creational Patterns
- 3 Structural Patterns
- 4 Behavioral Patterns
- 5 Anti-Patterns & Code Smells
